# History of Quantum Computing

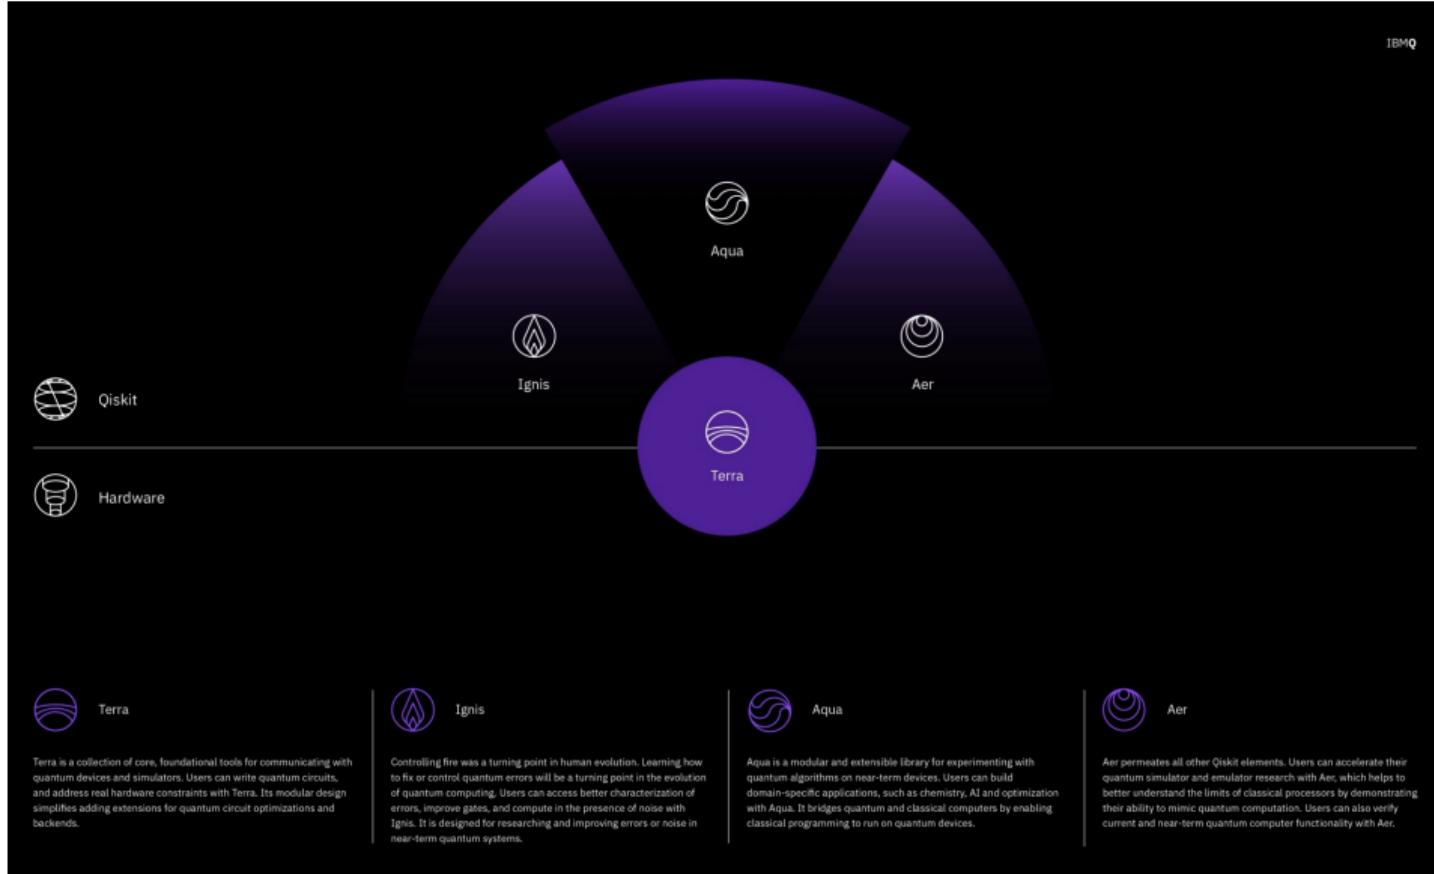

# What is Qiskit?

- ▶ SDK for working with Noisy Intermediate-Scale Quantum (NISQ) computers
- ▶ Provides a Python interface to write quantum programs
- ▶ Apache 2.0 License
- ▶ Designed to be backend agnostic
- ▶ Includes out-of-the-box local simulators and support for running on IBMQ

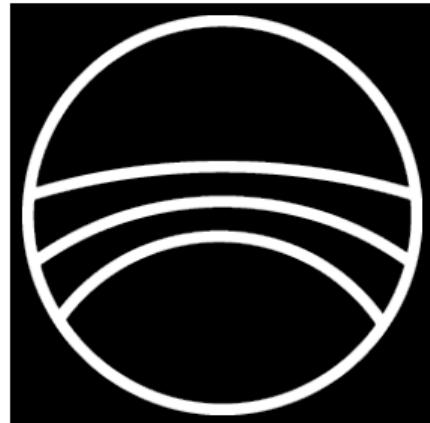

# Qiskit Elements

# Qiskit Terra

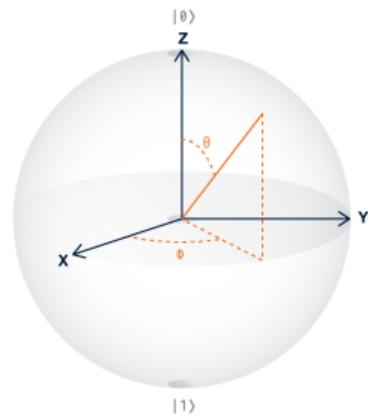

- ▶ Is the base layer for applications, provides interface to hardware and simulators
- ▶ Provides an SDK for working with quantum circuits
- ▶ Compiles circuits to run on different backends
- ▶

# The Qubit

- ▶ The bloch sphere provides a representation of qubit state
- ▶ State can be at any point along surface of sphere
- ▶ Measuring a qubit occurs along the Z axis. (also called basis states)
- ▶ Measuring a qubit is irreversible and will either be 0 or 1
- ▶ Qubits start at  $|0\rangle$

**Bloch Sphere:**

# Quantum Gates

- ▶ Quantum Logic Gates are used perform operations on qubits
- ▶ Each gate is reversible
- ▶

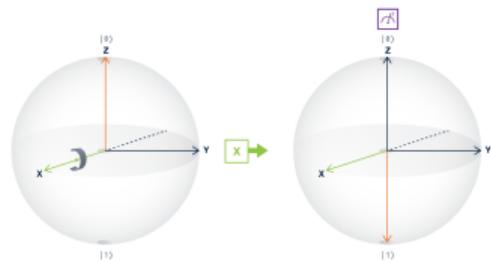

## Gate

$|0\rangle \xrightarrow{\boxed{X}} |1\rangle$

## Matrix Form

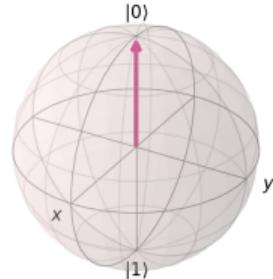

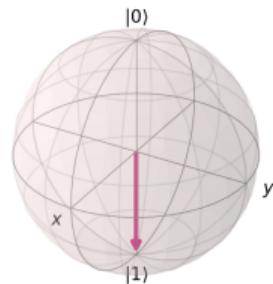

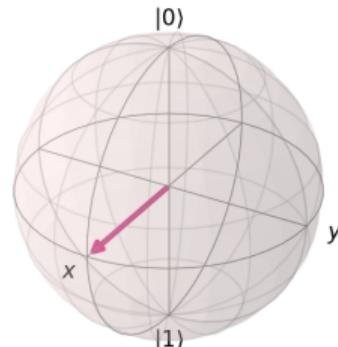

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

## Bloch Sphere

# Superposition

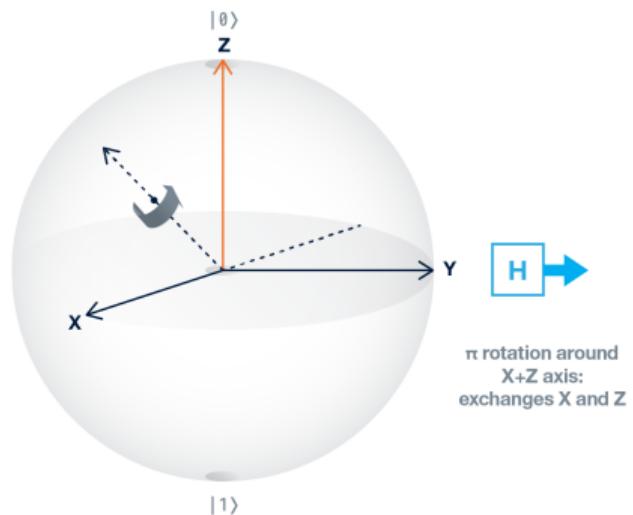

- ▶ Identically prepared qubits can still behave randomly
- ▶ The randomness is inherent in nature

$$|0\rangle$$

$$|1\rangle$$

$$|0\rangle + |1\rangle$$

# Hadamard Gate

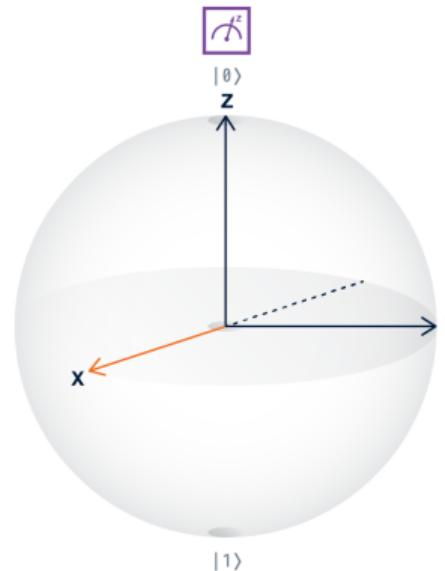

Gate

$|0\rangle \xrightarrow{H} |0\rangle$

Matrix Form

$$\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

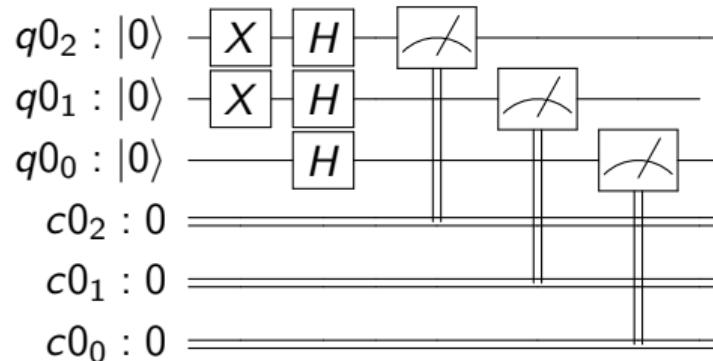

## Qubit Phase

- ▶ While qubits are read along the basis vectors there is dimension
- ▶ The phase can be leveraged to encode more information in the qubit

## Hadamard and Phase

# Quantum Circuits

Putting it together you build a circuit like:

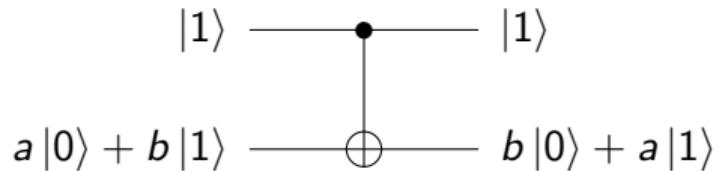

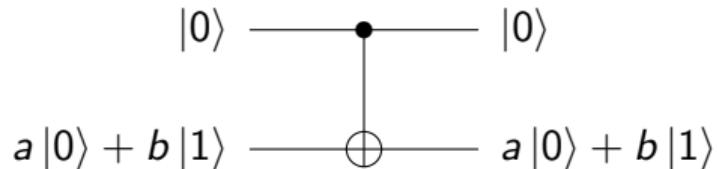

- ▶ Each row represents a bit, either quantum or classical
- ▶ The operations are performed each qubit left to right
- ▶ Shows dependencies of operations

## Multiple Qubits

# The Complexity and Power of Quantum Information

## Controlled Not Gate

CNOT flips the *target* bit if the *control* bit is 1

# Bernstein-Vazirani Algorithm<sup>1</sup>

Input (query)  
 $\Leftarrow X_{n-1} \dots X_1 X_0$

Secret Bitstring  
 $S_{n-1} \dots S_1 S_0$

Output (result)  
 $\Rightarrow X_{n-1}S_{n-1} \oplus \dots \oplus X_1S_1 \oplus X_0S_0$

**The Oracle**

---

<sup>1</sup>E. Bernstein & U. Vazirani, STOC, 93

# Optimal Classical Oracle

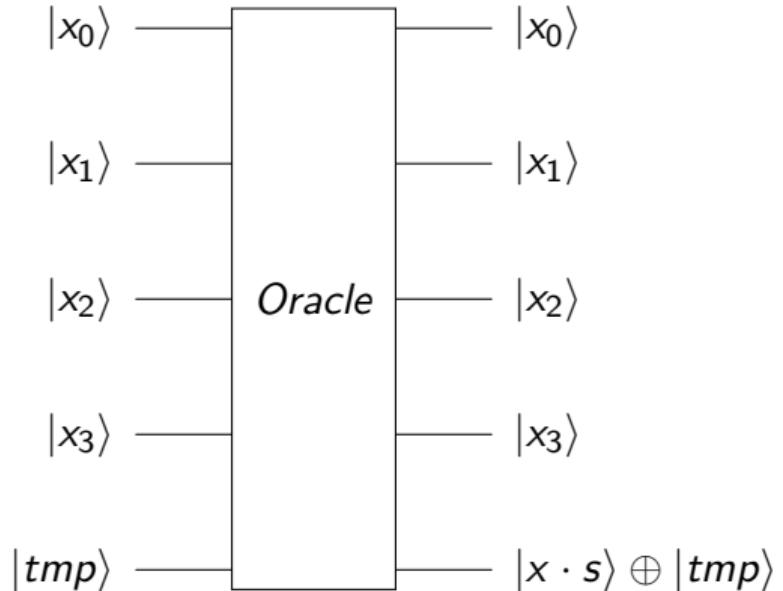

Loop over each bit!

$$\left\{ \begin{array}{ll} X = 1 0 \cdots 0 0 & (2^{n-1}) \\ X = 0 1 \cdots 0 0 & (2^{n-2}) \\ \vdots & \\ X = 0 0 \cdots 1 0 & (2) \\ X = 0 0 \cdots 0 1 & (1) \end{array} \right.$$

The ideal classical oracle is  $\mathcal{O}(n)$

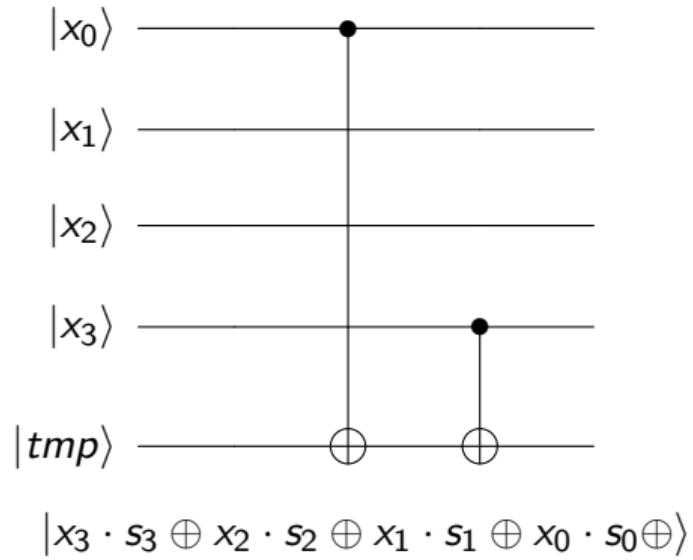

# Quantum Oracle

**A quantum oracle is  $\mathcal{O}(1)$**

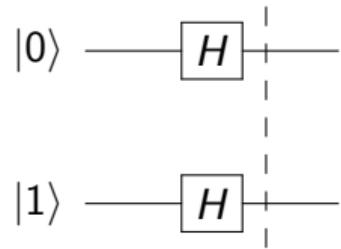

# Quantum Oracle Implementation

$$S = 0101$$

# Phase Kickback

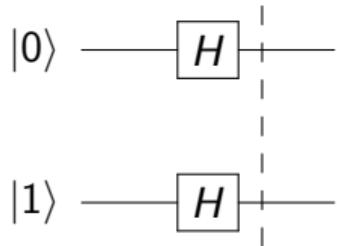

$$(|0\rangle + |1\rangle)(|0\rangle - |1\rangle)$$

## Phase Kickback

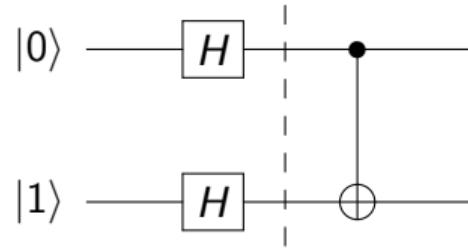

$$(|0\rangle + |1\rangle)(|0\rangle - |1\rangle) = |00\rangle - |01\rangle + |10\rangle - |11\rangle$$

Expand it

## Phase Kickback

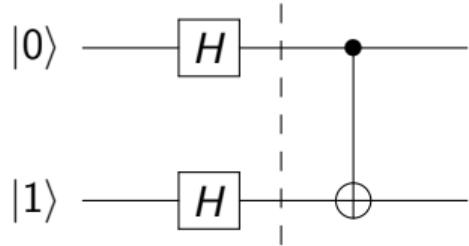

$$(|0\rangle + |1\rangle)(|0\rangle - |1\rangle) = |00\rangle - |01\rangle + |10\rangle - |11\rangle$$

$$|00\rangle - |01\rangle - |10\rangle + |11\rangle$$

## Phase Kickback

$$(|0\rangle + |1\rangle)(|0\rangle - |1\rangle) = |00\rangle - |01\rangle + |10\rangle - |11\rangle$$

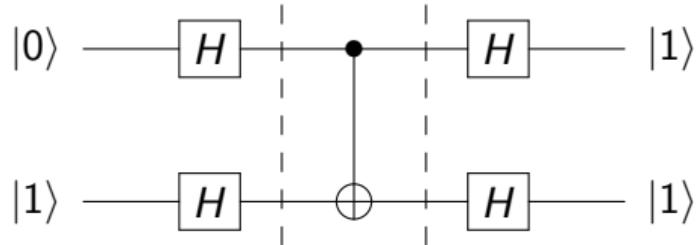

$$|00\rangle - |01\rangle - |10\rangle + |11\rangle = (|0\rangle - |1\rangle)(|0\rangle - |1\rangle)$$

Phase Kickback

## Phase Kickback

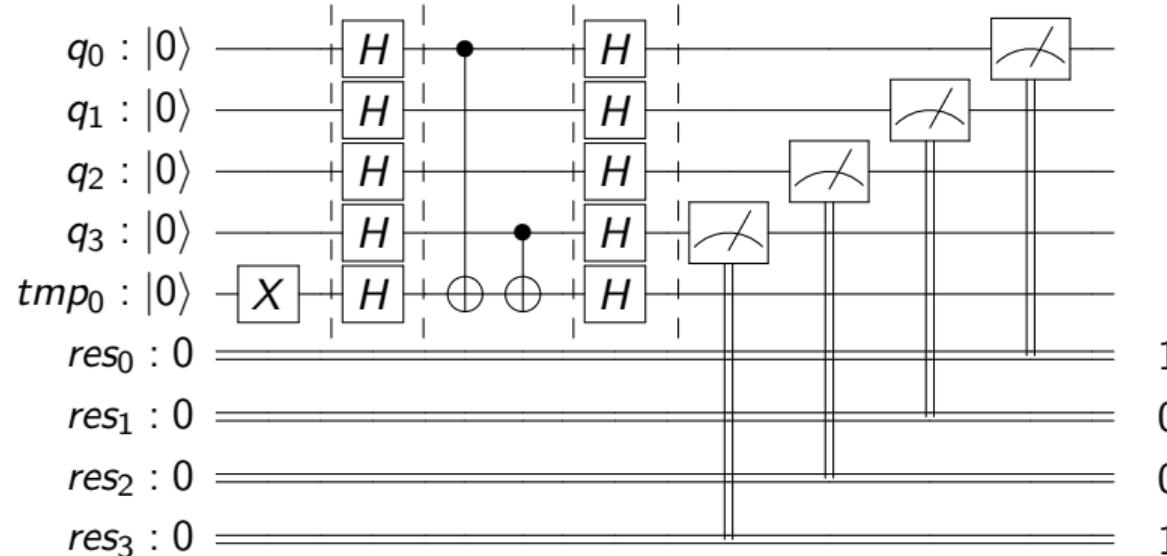

$$(|0\rangle + |1\rangle)(|0\rangle - |1\rangle) = |00\rangle - |01\rangle + |10\rangle - |11\rangle$$

$$|00\rangle - |01\rangle - |10\rangle + |11\rangle = (|0\rangle - |1\rangle)(|0\rangle - |1\rangle)$$

Phase Kickback

## Full Circuit for a Quantum Oracle

Where there is a CNOT phase kickback will set the control qubit to state  $|1\rangle$
